# Introduction and Motivation

# Introduction and Motivation

- Airfield rigid pavement design (FAARFIELD) based on:
  - FE analysis of individual gear loads;
  - Critical tensile stress at the bottom;
  - No thermal loads (flat slab condition);

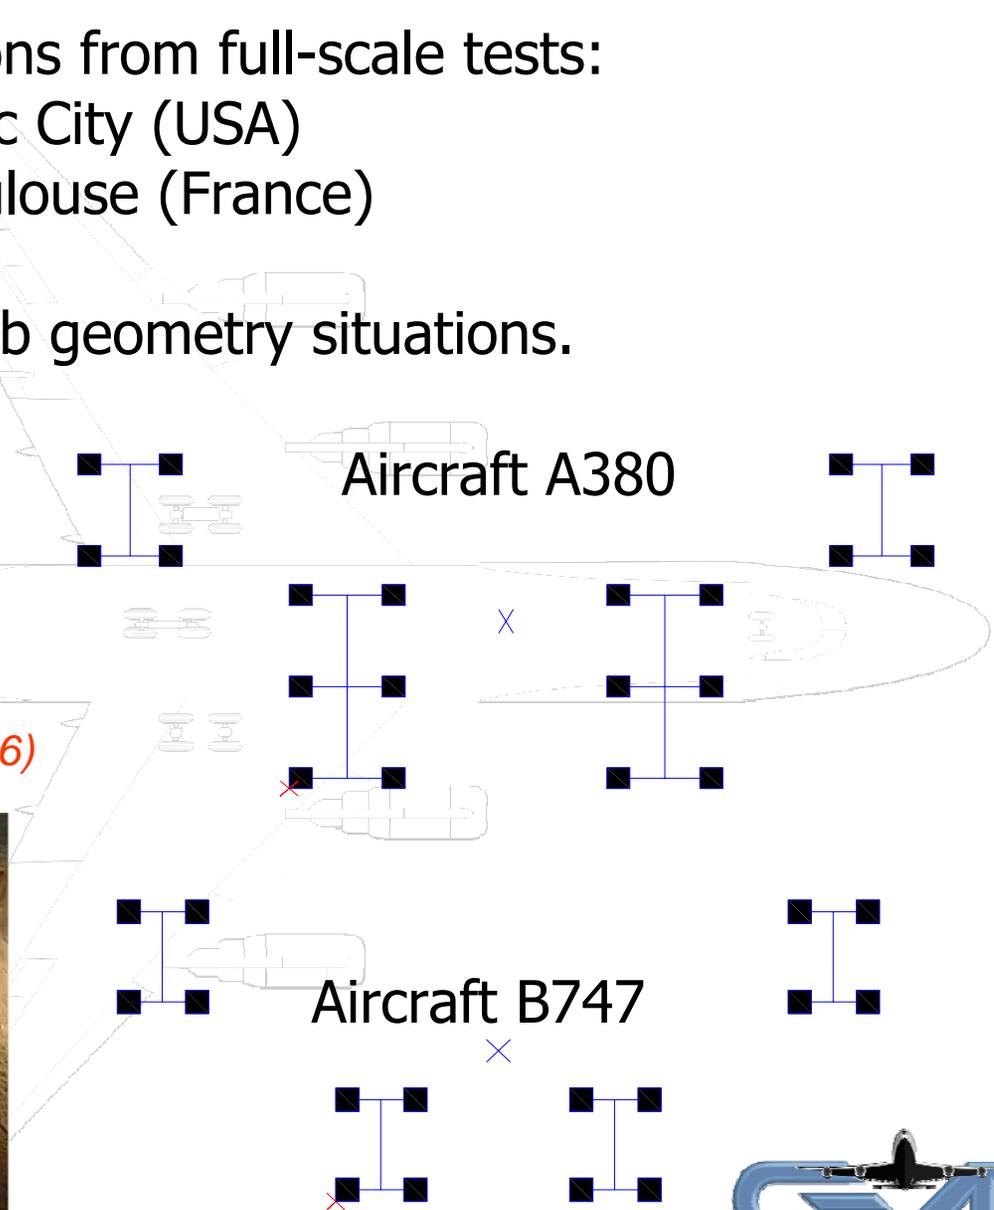

# Introduction and Motivation

- Top-Down cracking observations from full-scale tests:
  - FAA's NAPTF at Atlantic City (USA)
  - A-380 PEP tests at Toulouse (France)
- Certain combined load and slab geometry situations.

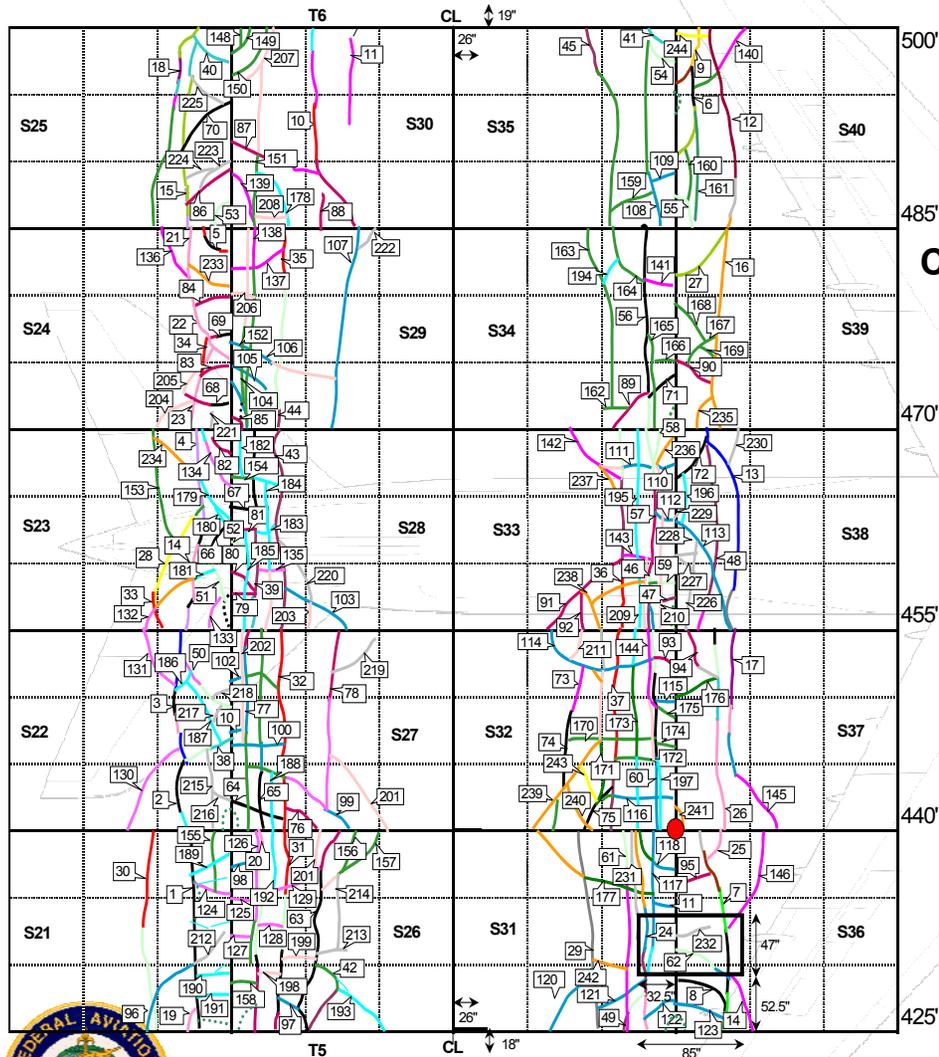

*from Dr. Ed Guo (2006)*

# Introduction and Motivation

- FAA's NAPTF Tests (CC2 - MRG)

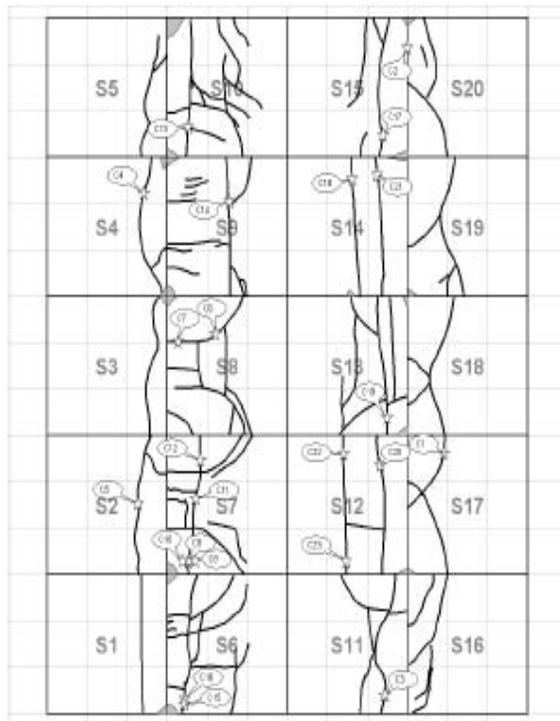

Tests and observed cracks in CC2 tests (Hayhoe and Garg, 2006)

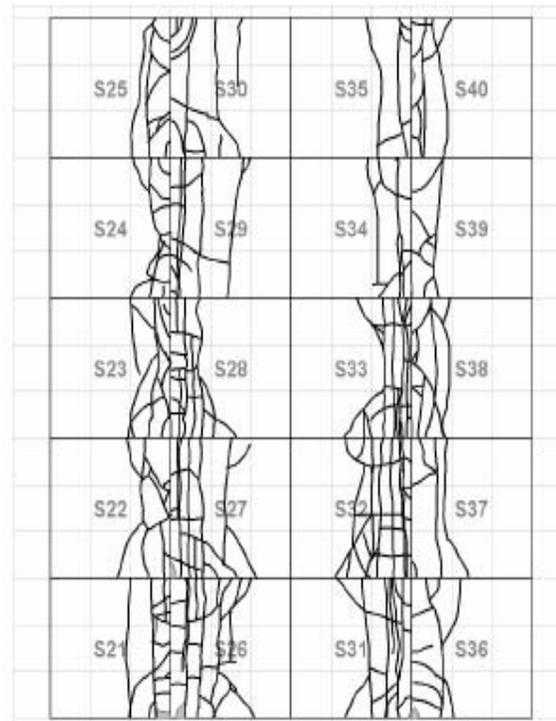

- Tridem and tandem gear loading

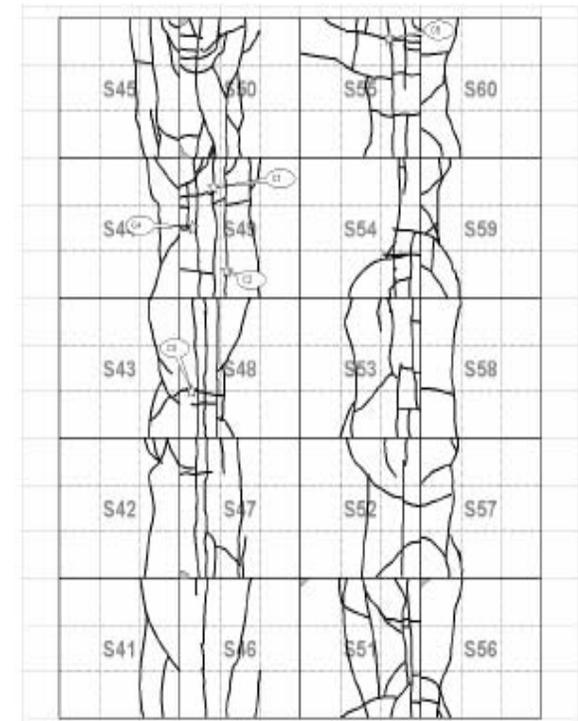

## FAA CC2 failure cracks (all sections)

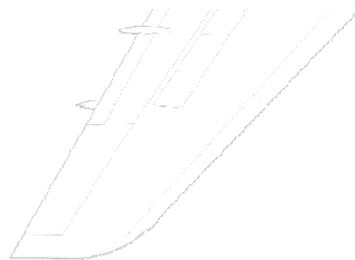

(a) Test Item MRC

(b) Test Item MRG

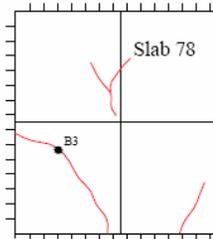

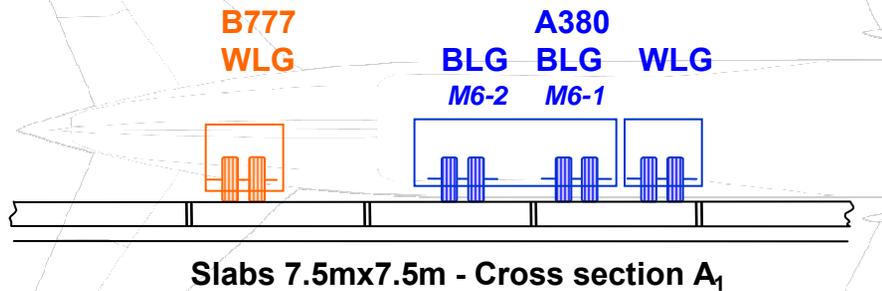

(c) Test Item MRS

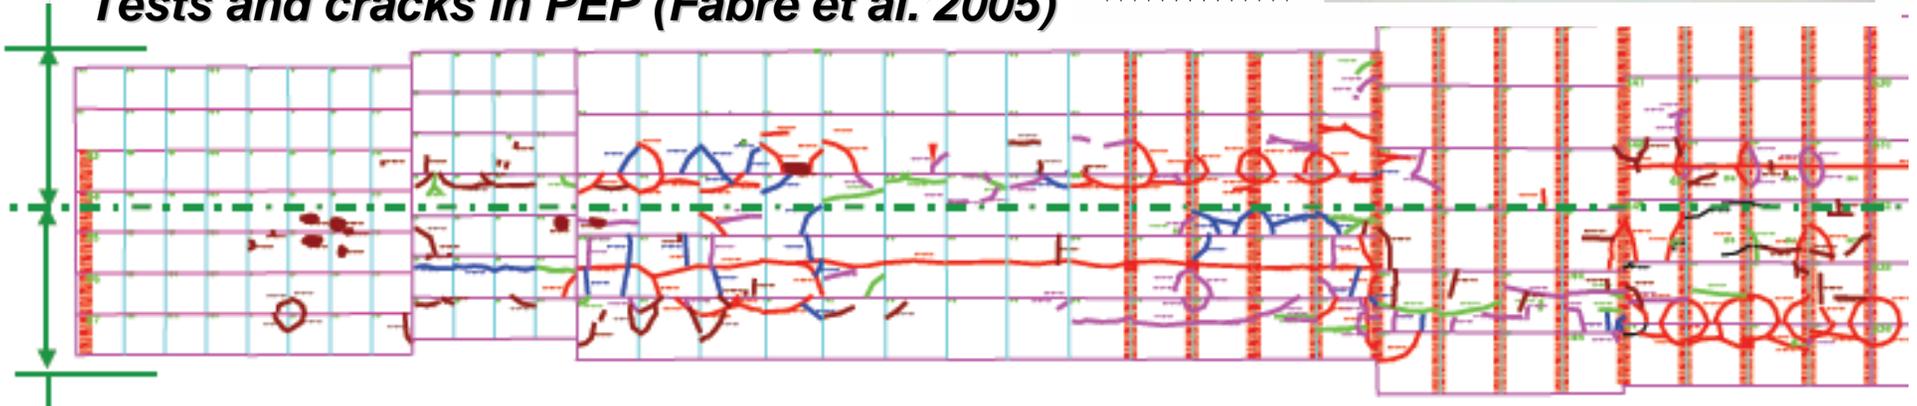

# Introduction and Motivation

- A-380 Pavement Experimental Programme - Rigid Phase (France)

**Tests and cracks in PEP (Fabre et al. 2005)**

# Objectives

# Objectives

- Identify key aircraft loading locations on rigid pavements which induce high top tensile stresses (ratio between top and bottom);
  - *NO CURLING (2-D and 3-D)*
  - *CURLING (2-D)*
- Investigate the quantitative effect of several parameters and their interaction on predicted critical tensile stresses and positions:
  - Slab Length: **L**
  - Load type: **individual gear versus full aircraft**;
  - Radius of Relative Stiffness,  **$\ell - (h,k)$**
  - Load Transfer Efficiency (**LTE**) between slabs:

$$LTE = \frac{\delta_{unloaded}}{\delta_{loaded}} \times 100$$

# Methodology

## Scenario's description

**A system of 4x4 slabs were simulated with ILLISLAB under different load conditions:**

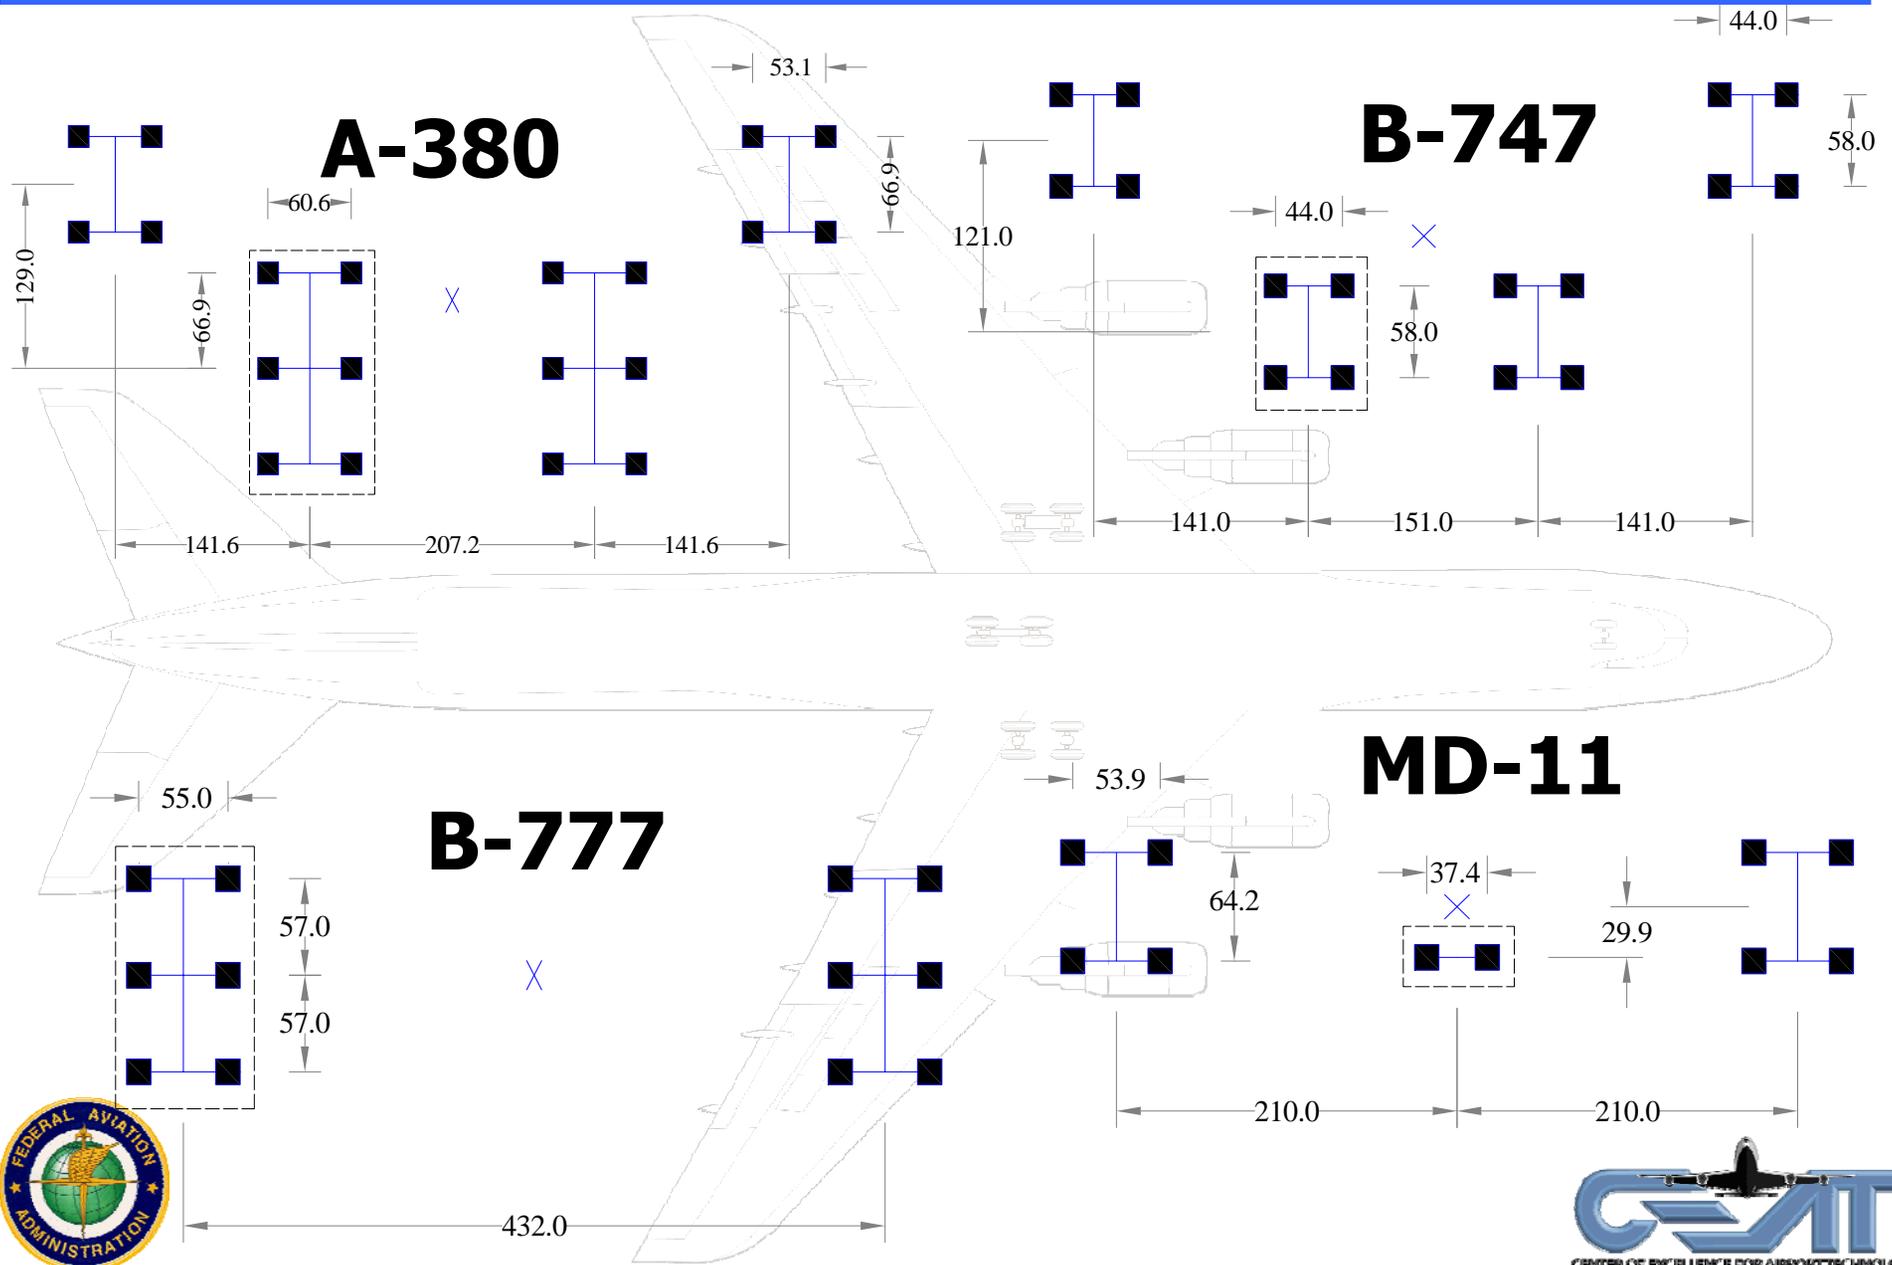

**Case I: Individual (single) gears** for the A-380 (TDT), B-747 (DT), B-777 (TDT), and MD-11 (D) aircraft were traversed over the central slab in both the x- and y- directions.

• **Case II:** All main landing gears (**full aircraft**) for the A-380, B-747, B-777, and MD-11 aircraft were also traversed over the central slab in both the x- and y- directions.

**The following properties were constant for all simulations:**

- Concrete elastic properties:  $E_c = 4.5 \times 10^6$  psi and  $u = 0.15$
- Tire contact pressure:  $p = 200$  psi
- Tire geometry: length = width = 15 in.
- Wheel load per tire:  $P = 45,000$  lbs

# Aircraft configurations

# Structural Analysis (Finite Element)

- **2-D Finite Element Analysis - ILLISLAB**

- Tabatabaie (1979) and Khazanovich and Ioannides (1994);

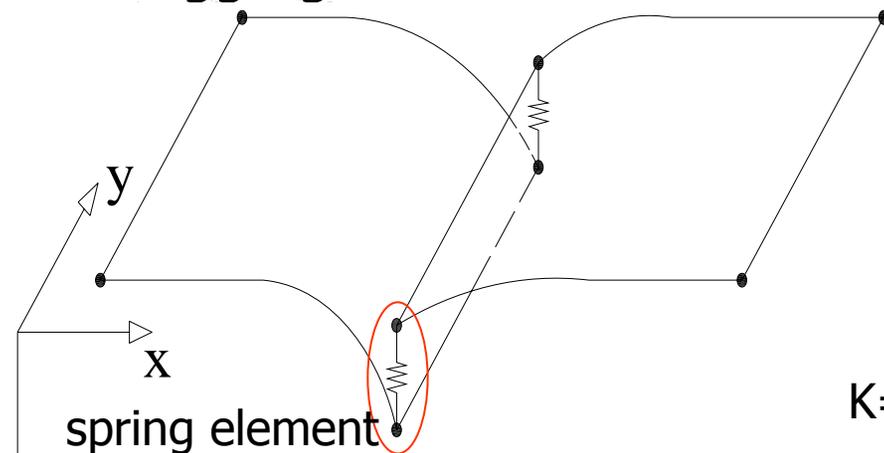

- Medium Thick Plate Theory

- Kirchoff plate assumptions

- 4-noded, 12-dof plate bending element.

- Multiple plates (joint simulation):

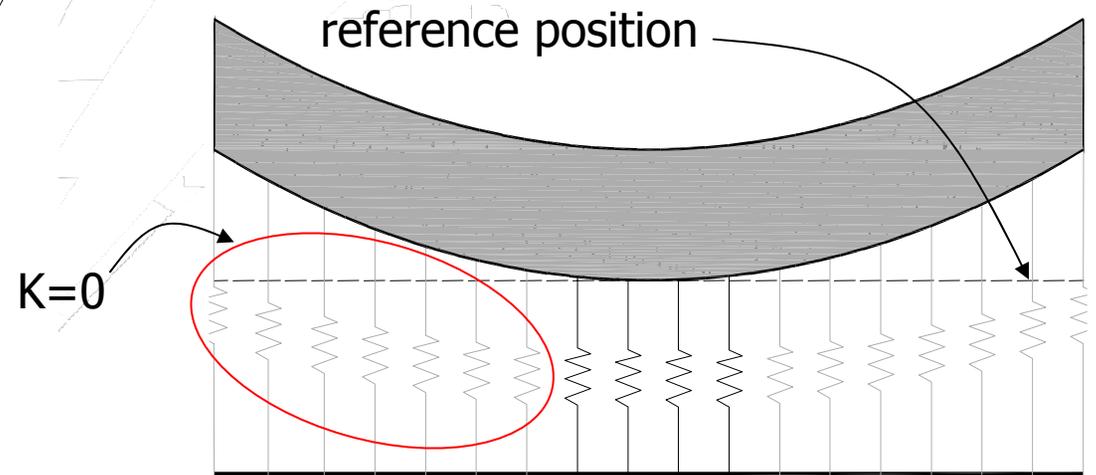

- aggregate interlock:

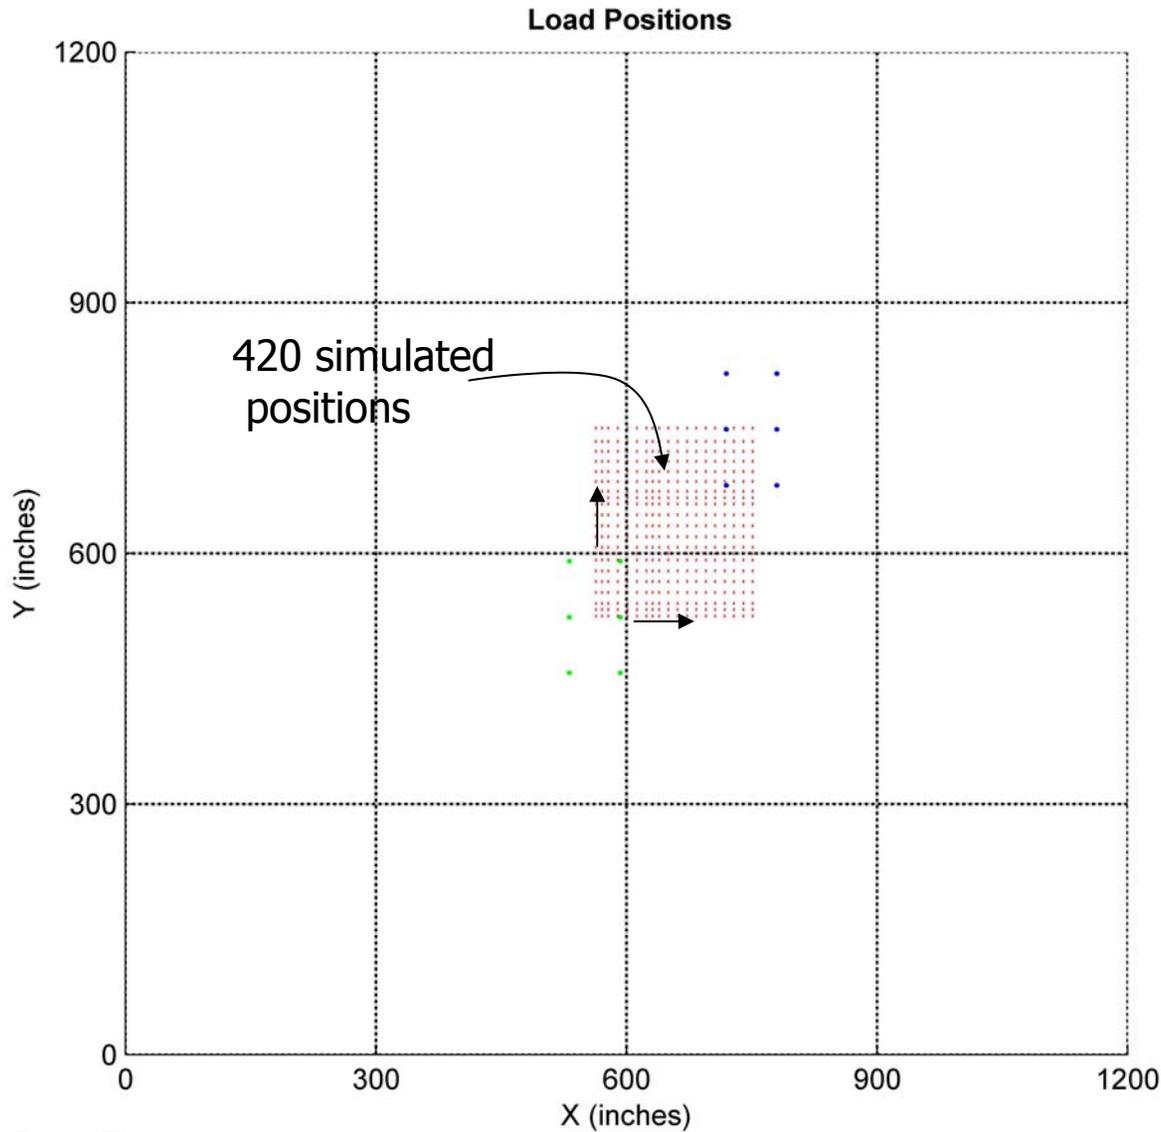

$$LTE = \frac{\delta_{unloaded}}{\delta_{loaded}} \times 100\%$$

- Curling (loss of contact):

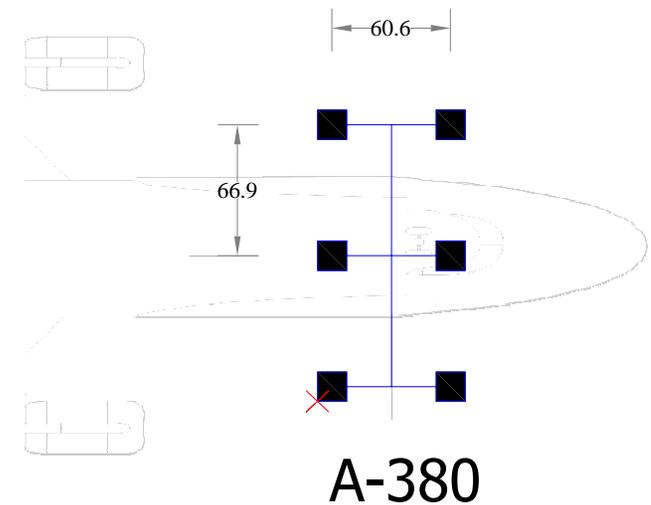

- mechanical+thermal+body loadings

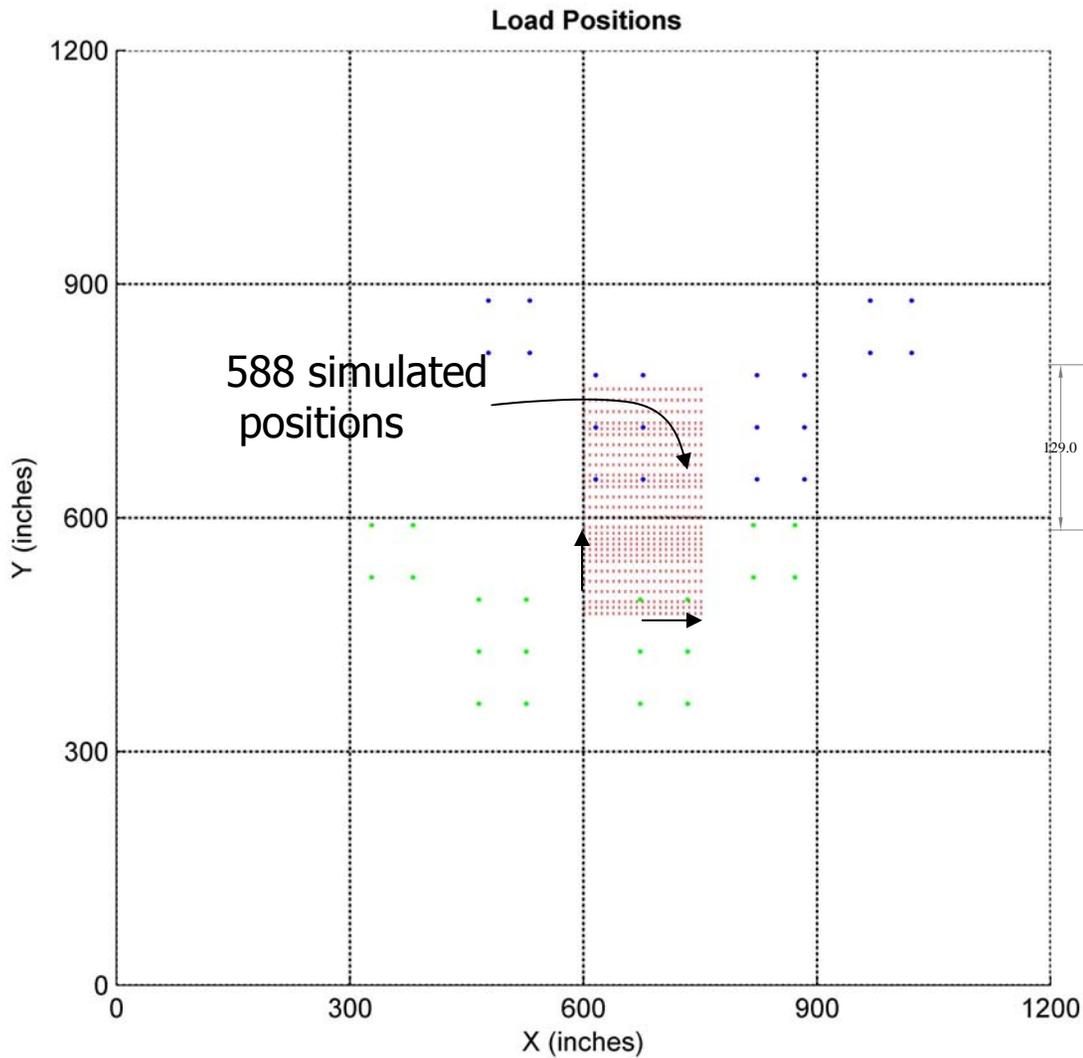

# Load Type: Single Gear (e.g. A-380)

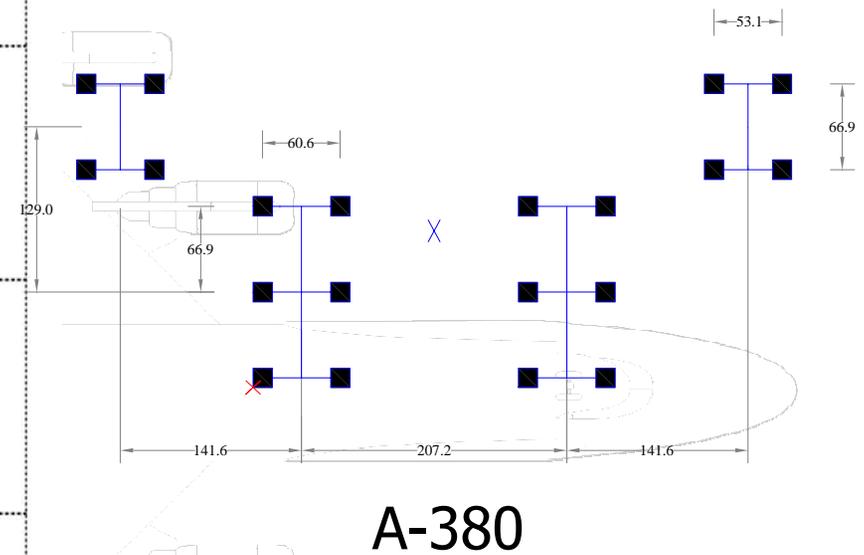

- Single gear traverses an inner slab

# Load Type: Full Aircraft (e.g. A-380)

- Full Aircraft traverses an inner slab

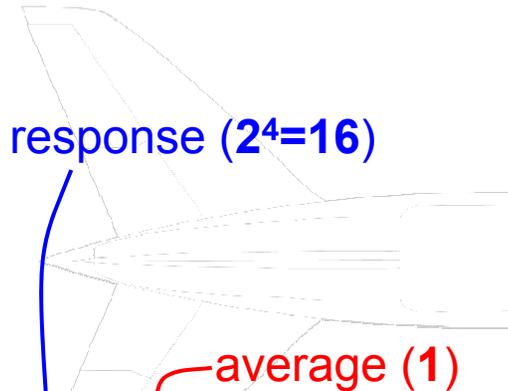

# Factorial Analysis

A 2<sup>4</sup> factorial design (4 factors at 2 levels each one) were used to investigate the effect of the below factors as well their interaction for the critical stress value and location:

| Level    | Slab length (L) | Radius of relative stiffness (ℓ) <sup>a</sup> | Load Transfer Efficiency (LTE) | Load Configuration (LC) |
|----------|-----------------|---|--------------------------------|-------------------------|
| -        | in. (m)         | in. (m)                                       | %                              | -                       |
| Low (-)  | 240 (6.10)      | 57 <sup>b</sup> (1.44)                        | 85                             | Single gear             |
| High (+) | 300 (7.62)      | 89 <sup>c</sup> (2.26)                        | 0                              | Full aircraft           |

response (2<sup>4</sup>=16)

<sup>a</sup>  $\ell = \sqrt{\frac{Eh}{12(1-\nu^2)k}}$  where E is the Young modulus for the slab, h is the thickness, ν is the Poisson ratio,

and k is the modulus of subgrade reaction;

<sup>b</sup> calculated using k = 150 psi/in (40.7 MPa/m), and h = 16 inches (40.6 cm);

<sup>c</sup> calculated using k = 50 psi/in (13.6 MPa/m), and h = 20 inches (50.8 cm).

$$Y = \mu + \sum_{i=1}^4 \alpha_i x_i + \sum_{i<j}^4 \alpha_{ij} x_i x_j + \sum_{i<j<k}^4 \alpha_{ijk} x_i x_j x_k + \sum_{i<j<k<l}^4 \alpha_{ijkl} x_i x_j x_k x_l$$

1<sup>st</sup> order (4)

$\alpha_1: L$

2<sup>nd</sup> order (6)

$\alpha_{12}: L-\ell$

3<sup>rd</sup> order (4)

4<sup>th</sup> order (1)

$\alpha_2$  Relative Effect

$$\overline{E}_f = \frac{\alpha}{\mu} \times 100\%$$

# Results (no curling)

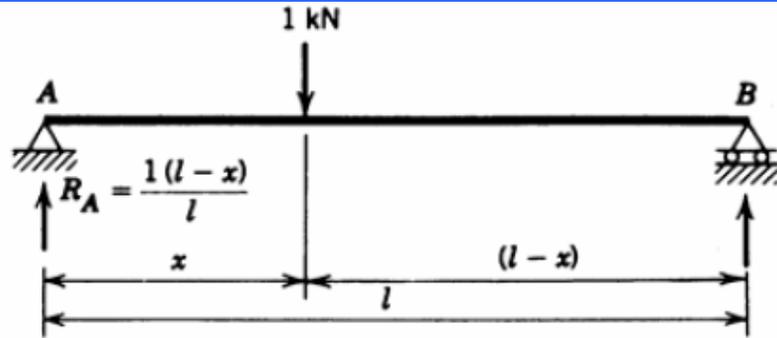

# Top to Bottom Stresses (t/b)

- Maximum tensile stresses were on the slab bottom for all single gear simulations;
- Single gear results: TDT of the B-777 and A-380 gear produced the highest ratios;
- Higher t/b stress ratios for no LTE;
- Full aircraft results: t/b ratios increased significantly for almost all aircrafts, but the B-777;
- A-380 induced similar tensile stresses at the top and bottom when LTE=0%.

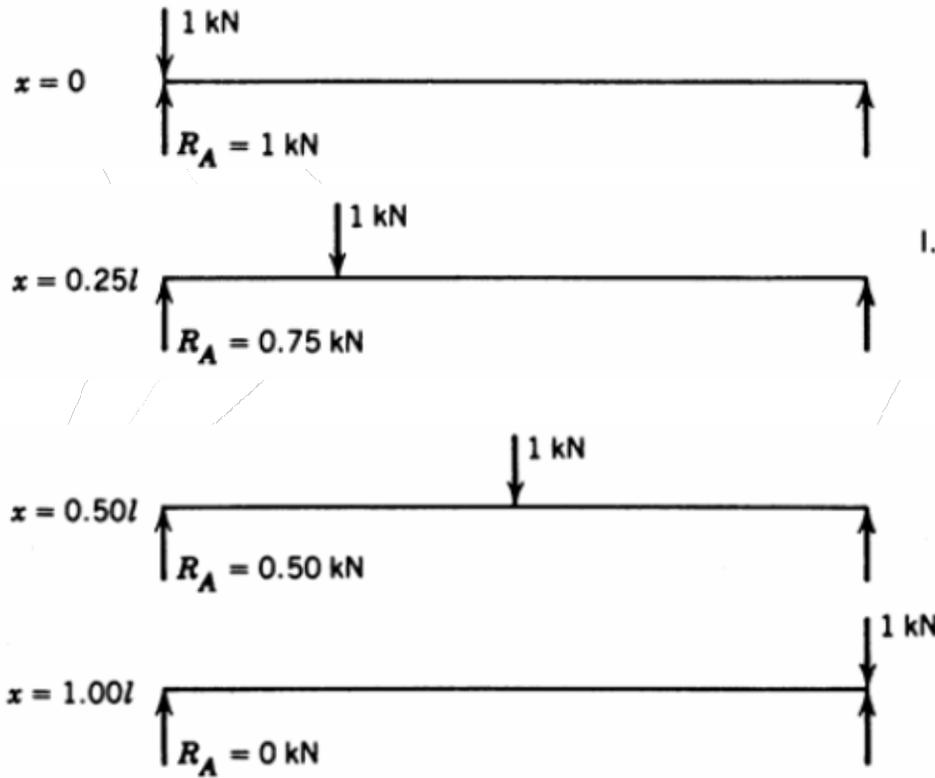

- full a/c;  
- LTE=0%;  
-  $\sigma_{xx}$  critical;  
- A-380 or MD-11

| Factors             |                     |         |          | Aircrafts   |                   |       |                   |

# Load Position: Influence Lines (1D)

How the **movement** of a unit **load influences** a force effect (reaction, shear, bend moment...) at one point.

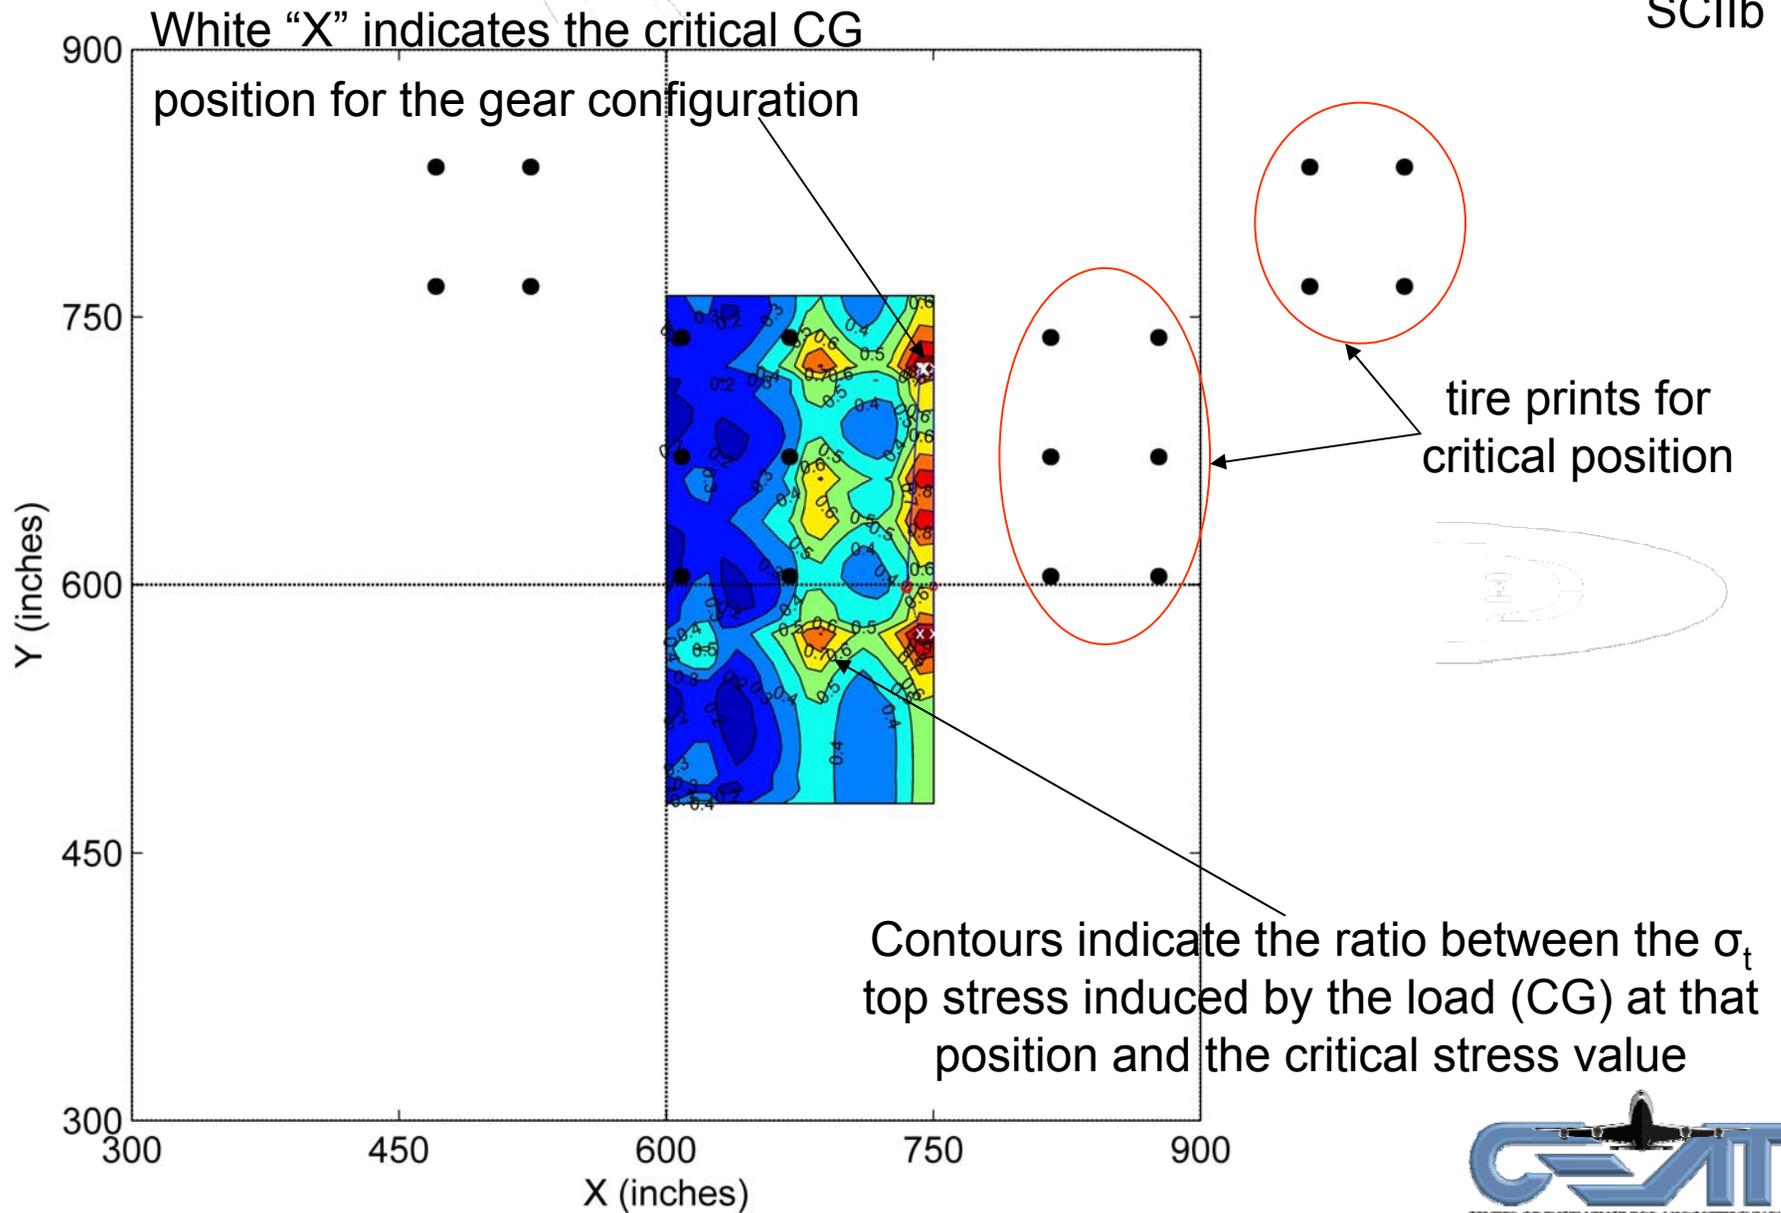

Influence line of reaction A at  $x=0$

one can tell **where** the **load** should be **placed** to induce the **greatest** influence ( $R_A$ ) at the specified point ( $x=0$ ).

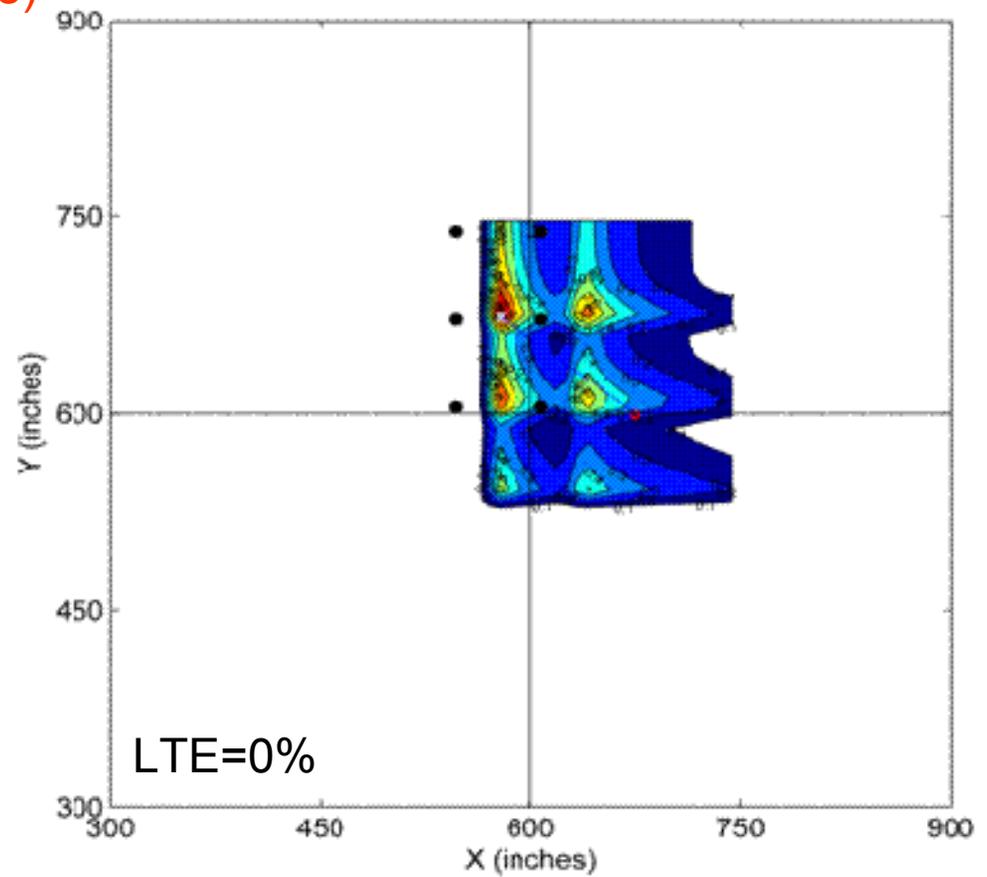

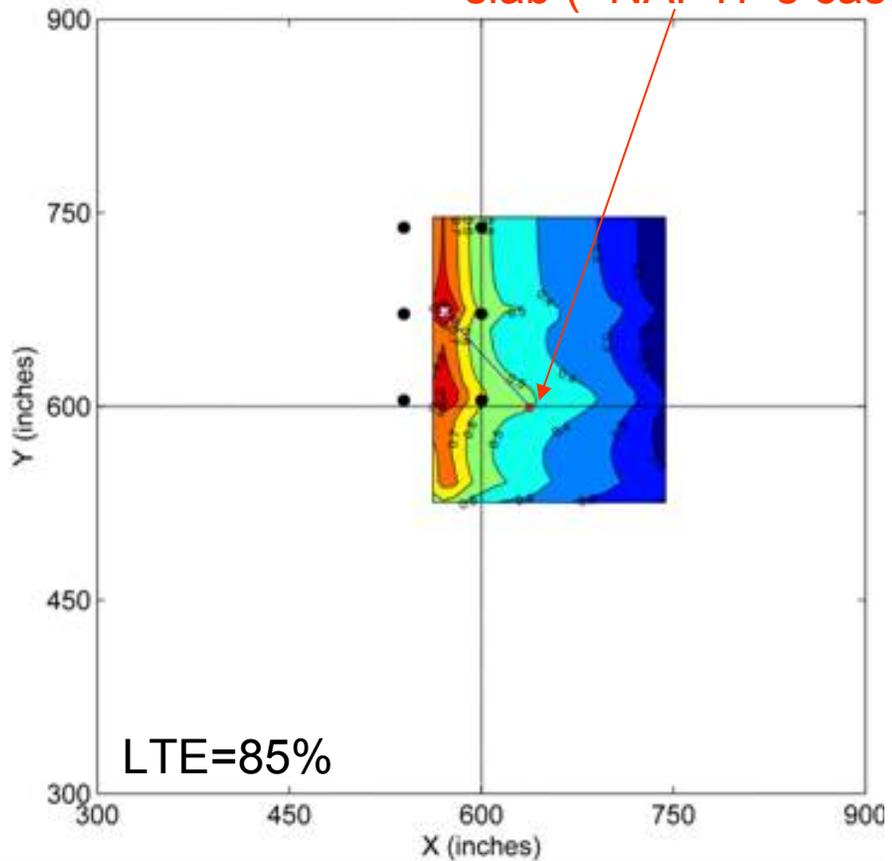

# Load Position Influence Graphs

SCIIb

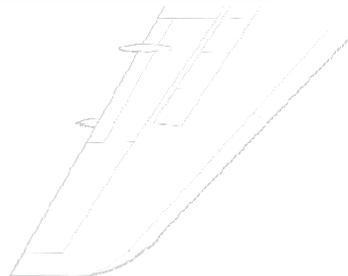

# Load Position Influence Graphs – Single gear

## **A-380 (TDT)** Critical top stress at the adjacent slab (~NAPTF's case)

- t/b ratios around 0.48

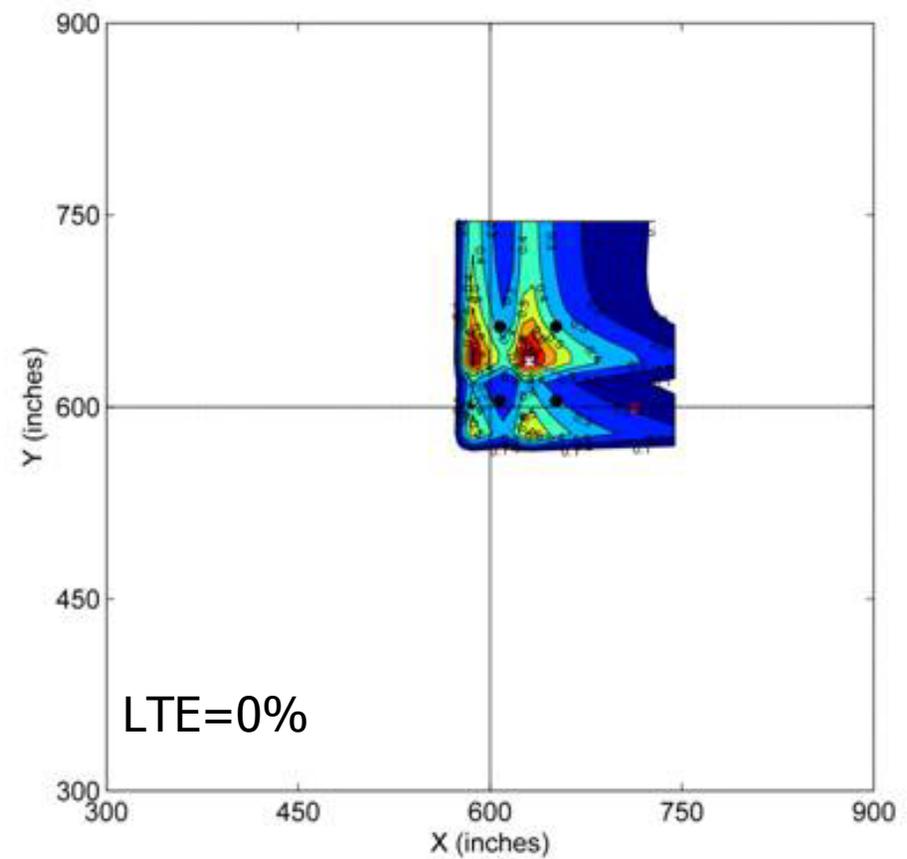

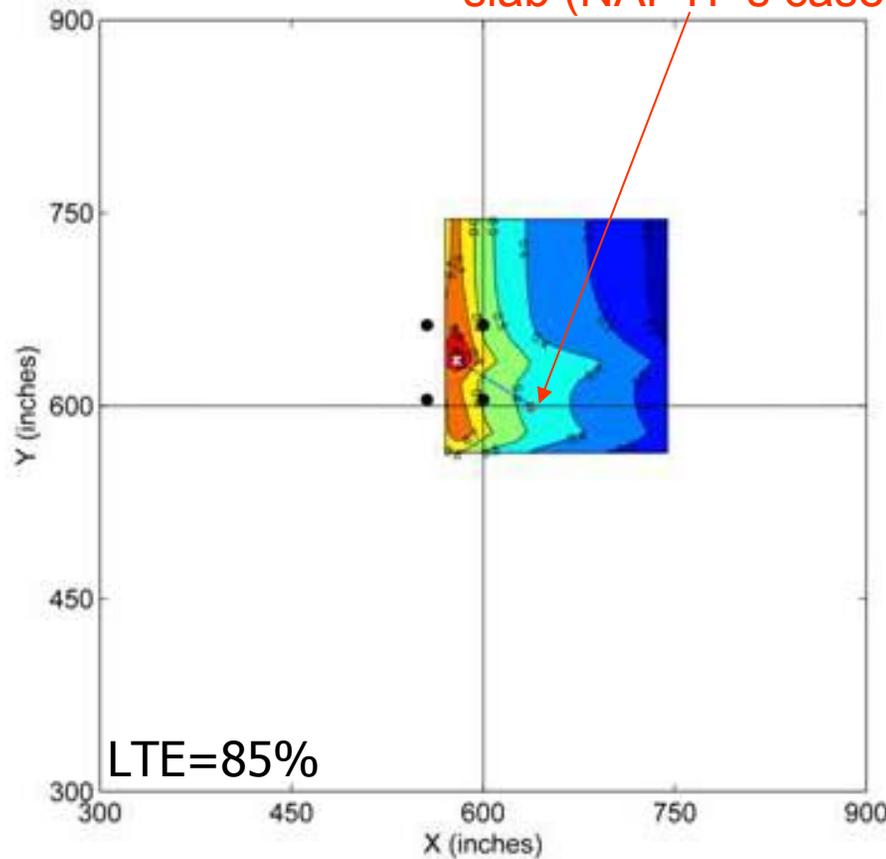

- t/b ratios around 0.67

# Load Position Influence Graphs – Single gear

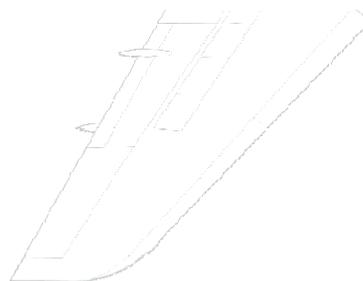

## **B-747 (DT)**

Critical top stress at the adjacent slab (NAPTF's case)

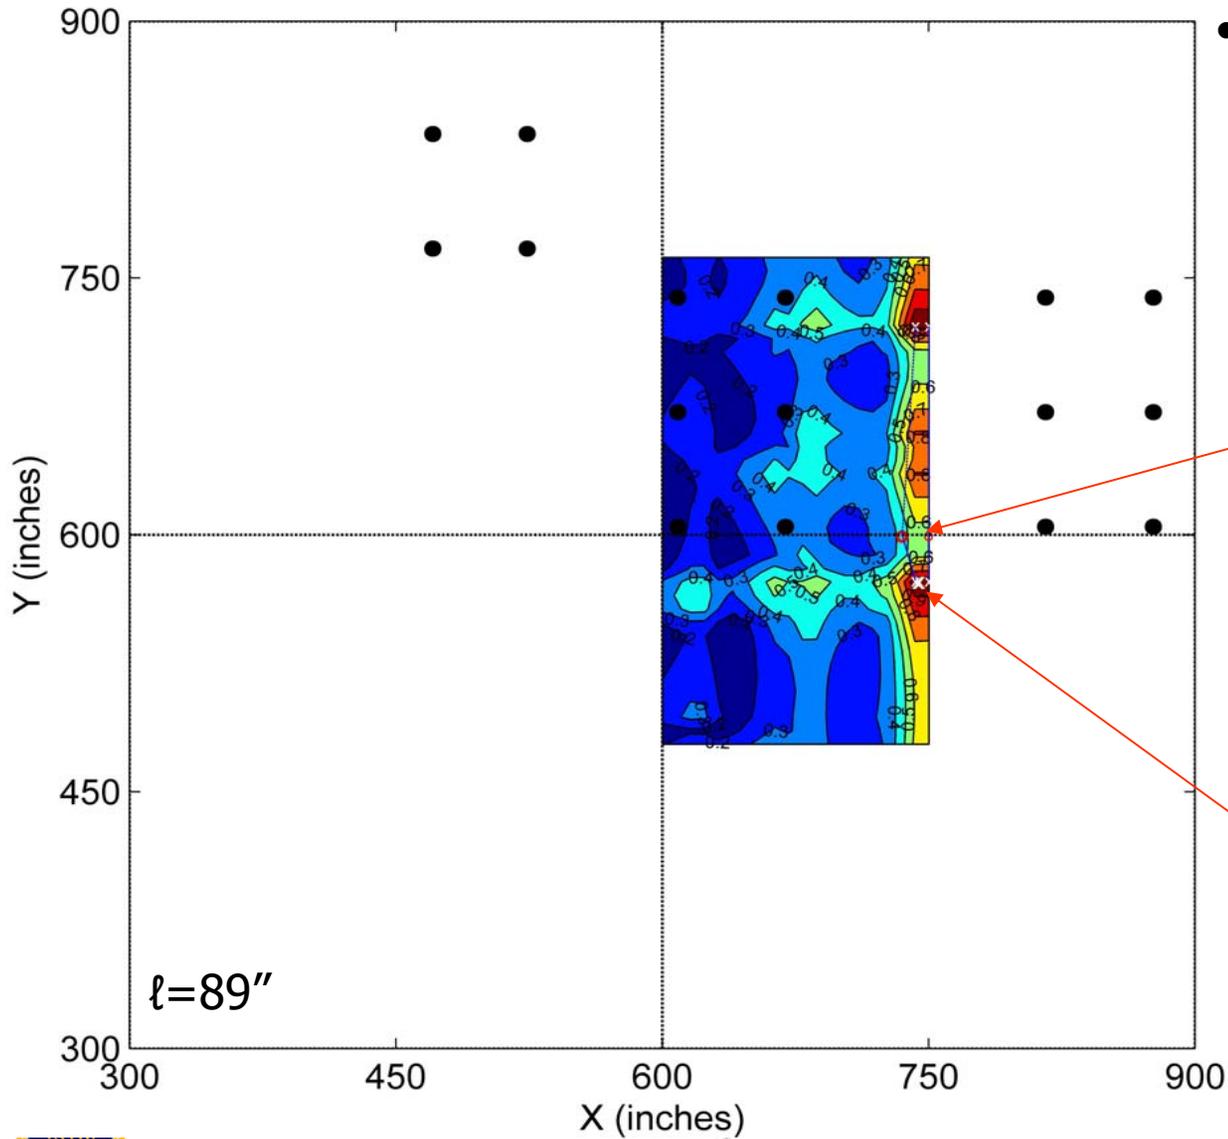

- t/b ratios around 0.45.

- t/b ratios around 0.60.

# Load Position Influence Graphs – Full A/C

## **A-380: $L = 300''$ and $LTE = 0\%$**

• t/b ratio=1.04.

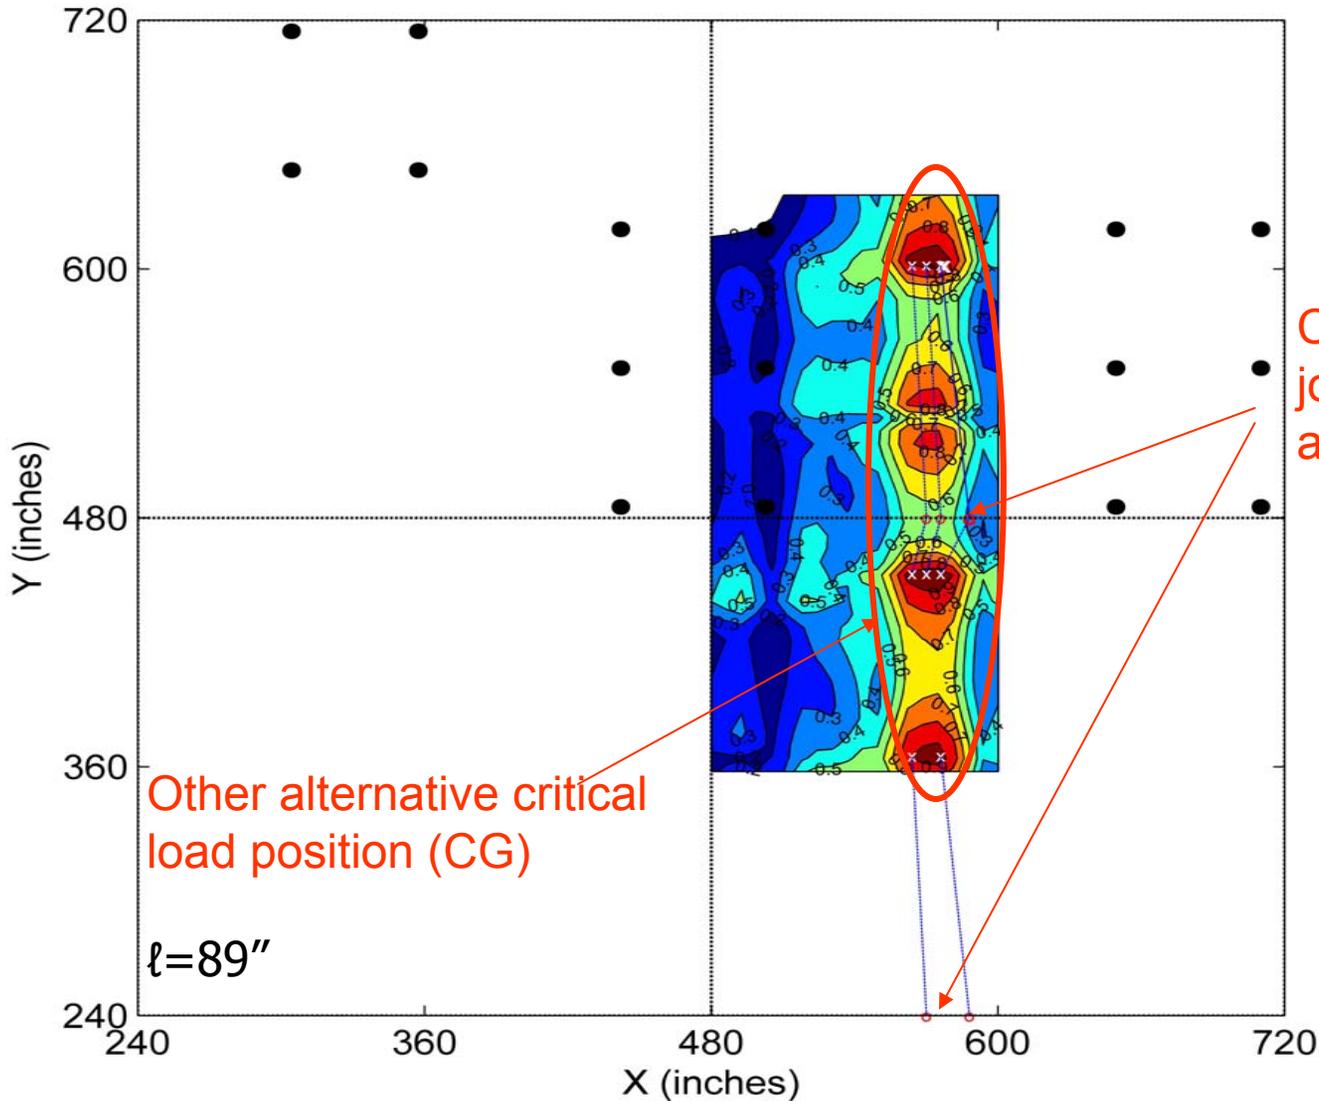

Critical stress at transverse joint → longitudinal cracking at mid-slab

Another alternative critical load position (CG)

# Load Position Influence Graphs – Full A/C

**A-380:  $L = 240''$  and  $LTE = 0\%$**

•  $t/b$  ratio = 1.00

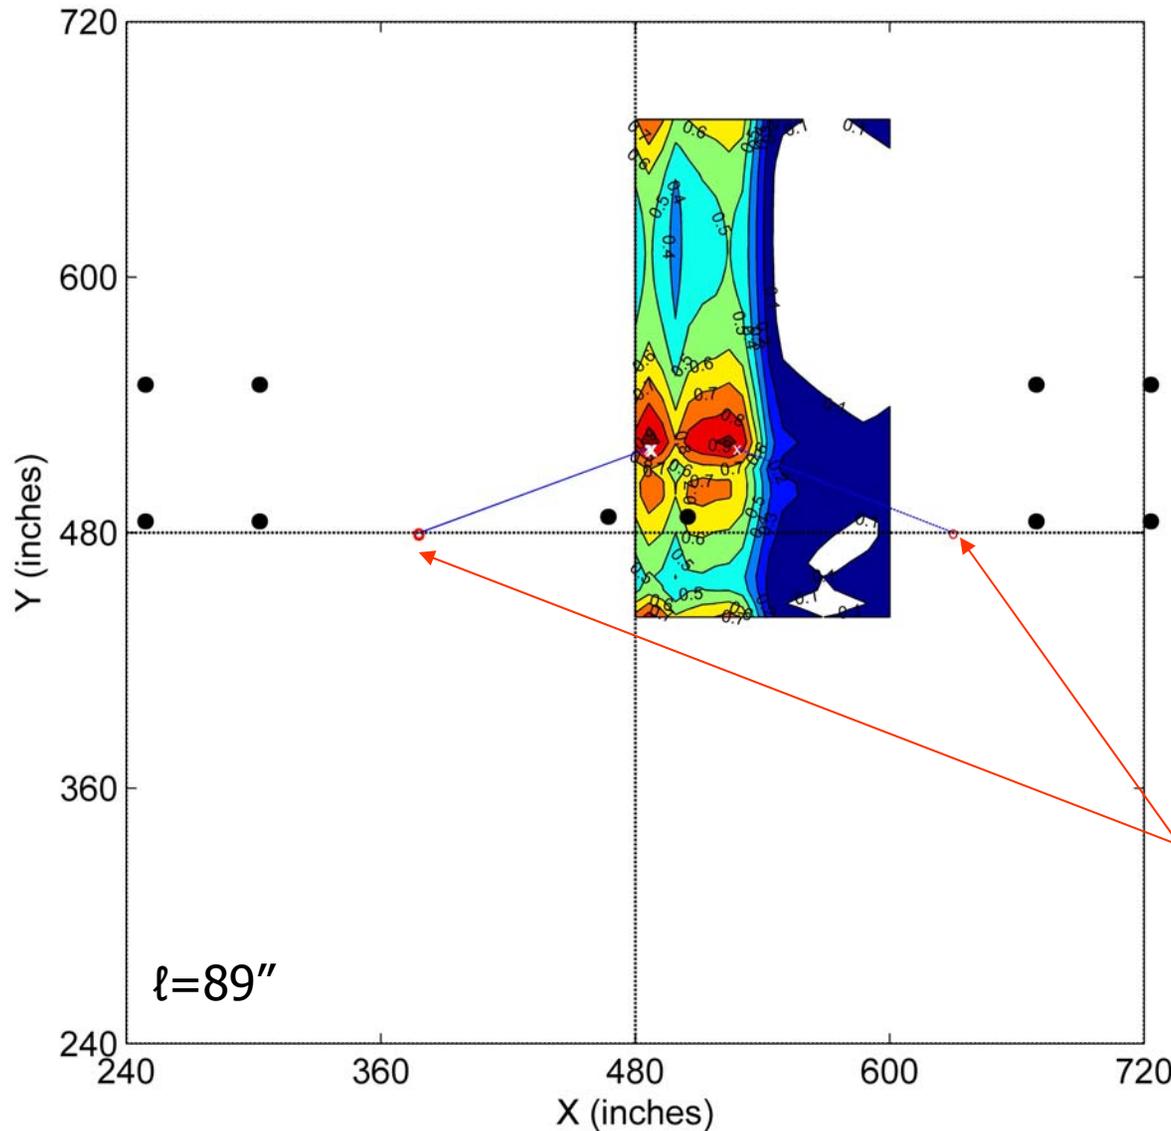

Critical stress at transverse joint → longitudinal cracking at mid-slab

Other alternative critical load position (CG)

# Load Influence Graphs – Full A/C

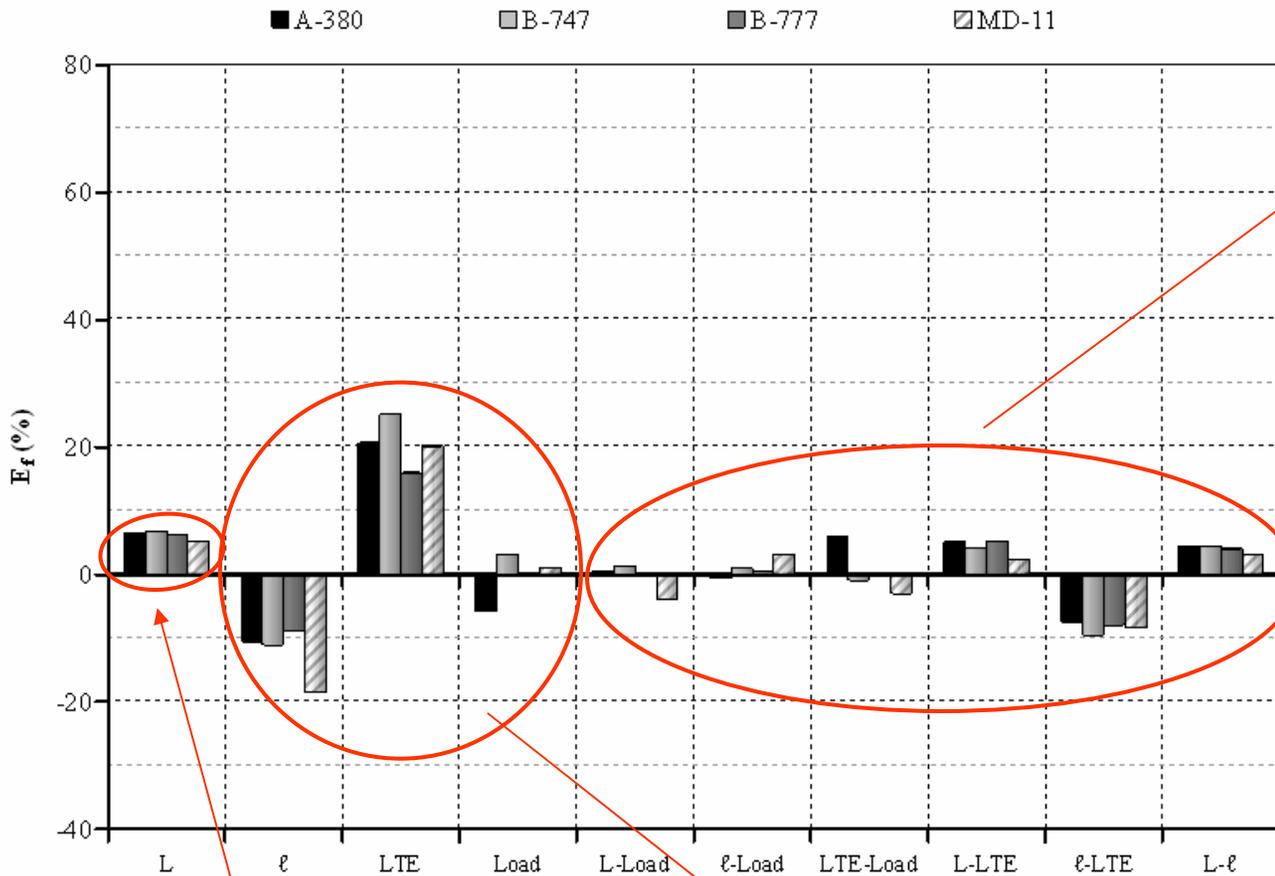

**MD-11:  $L = 240''$  and  $LTE = 0\%$**

- $t/b$  ratio = 0.86.

Critical stress at transverse joint → longitudinal cracking at mid-slab

# Factorial results (bottom tensile stress)

Few significant 2<sup>nd</sup> order interactions:

- L-LTE: for all A/C;
- l-LTE: for ALL A/C

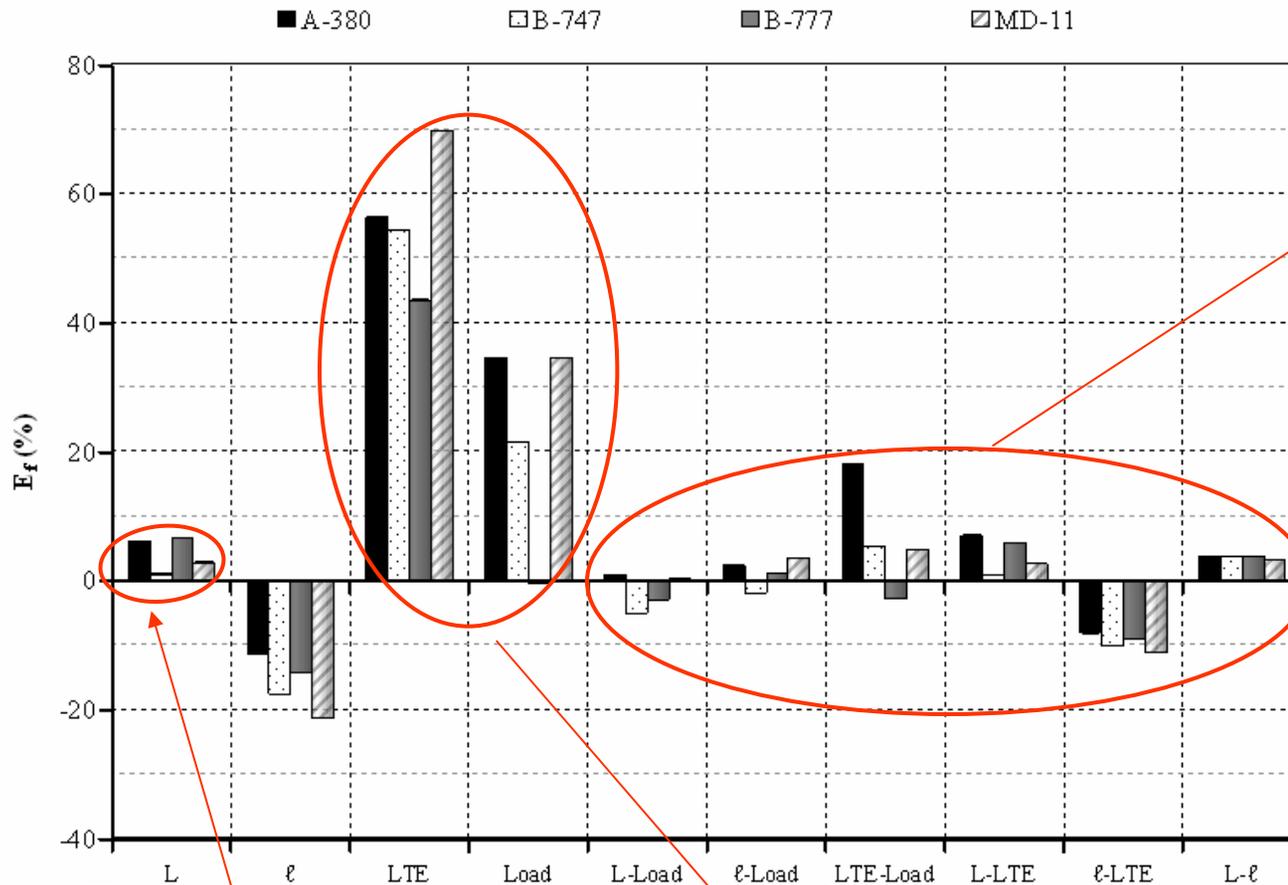

- little effect of L on bottom tensile stress

- LTE affects bottom tensile stress for all A/C
- Full gear has little effect on bottom stresses

No need to determine critical positions

# Factorial results (top tensile stresses)

Few significant 2<sup>nd</sup> order interactions:

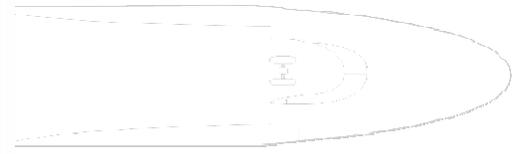

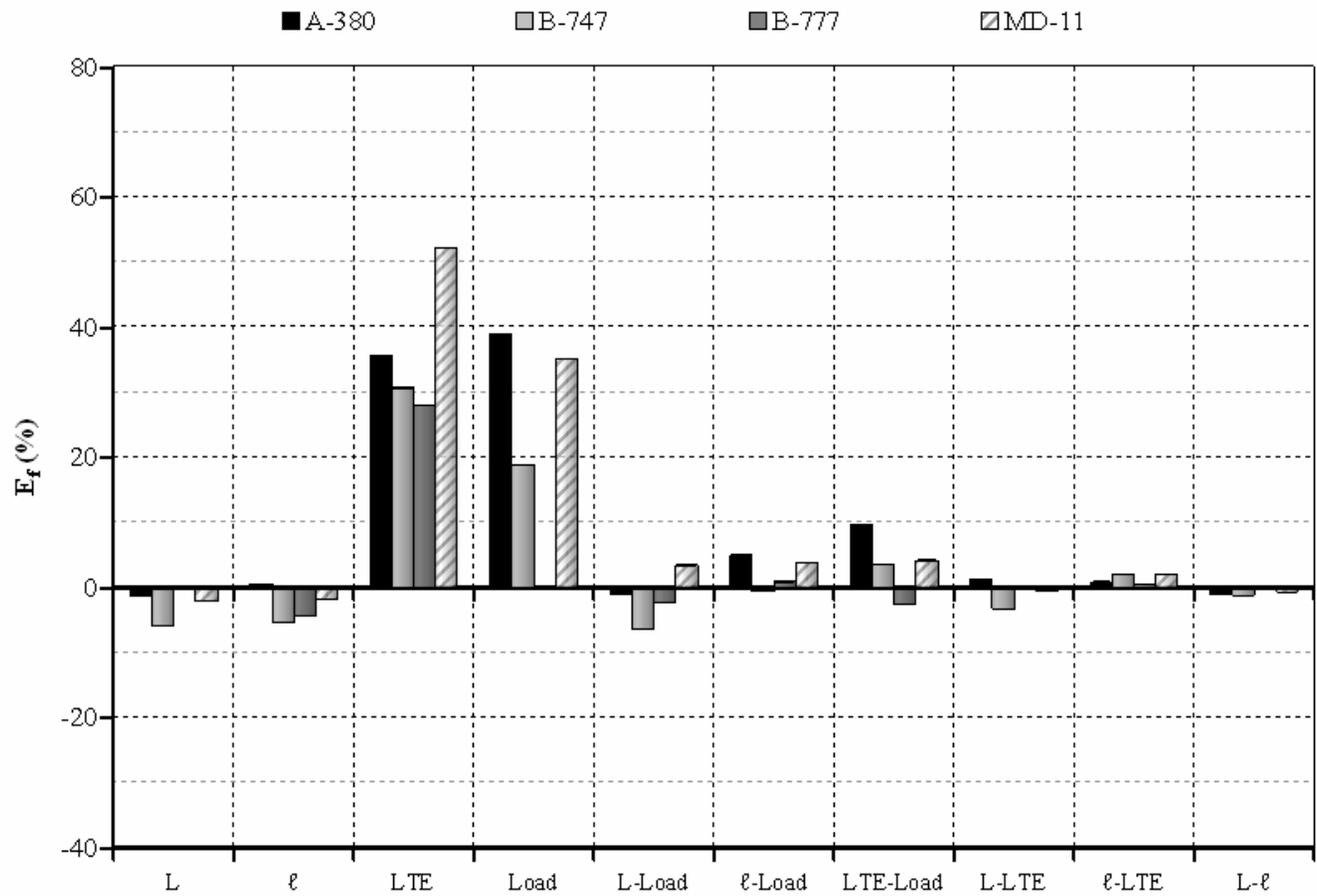

- Load-LTE: for A-380
- l-LTE: for ALL A/C

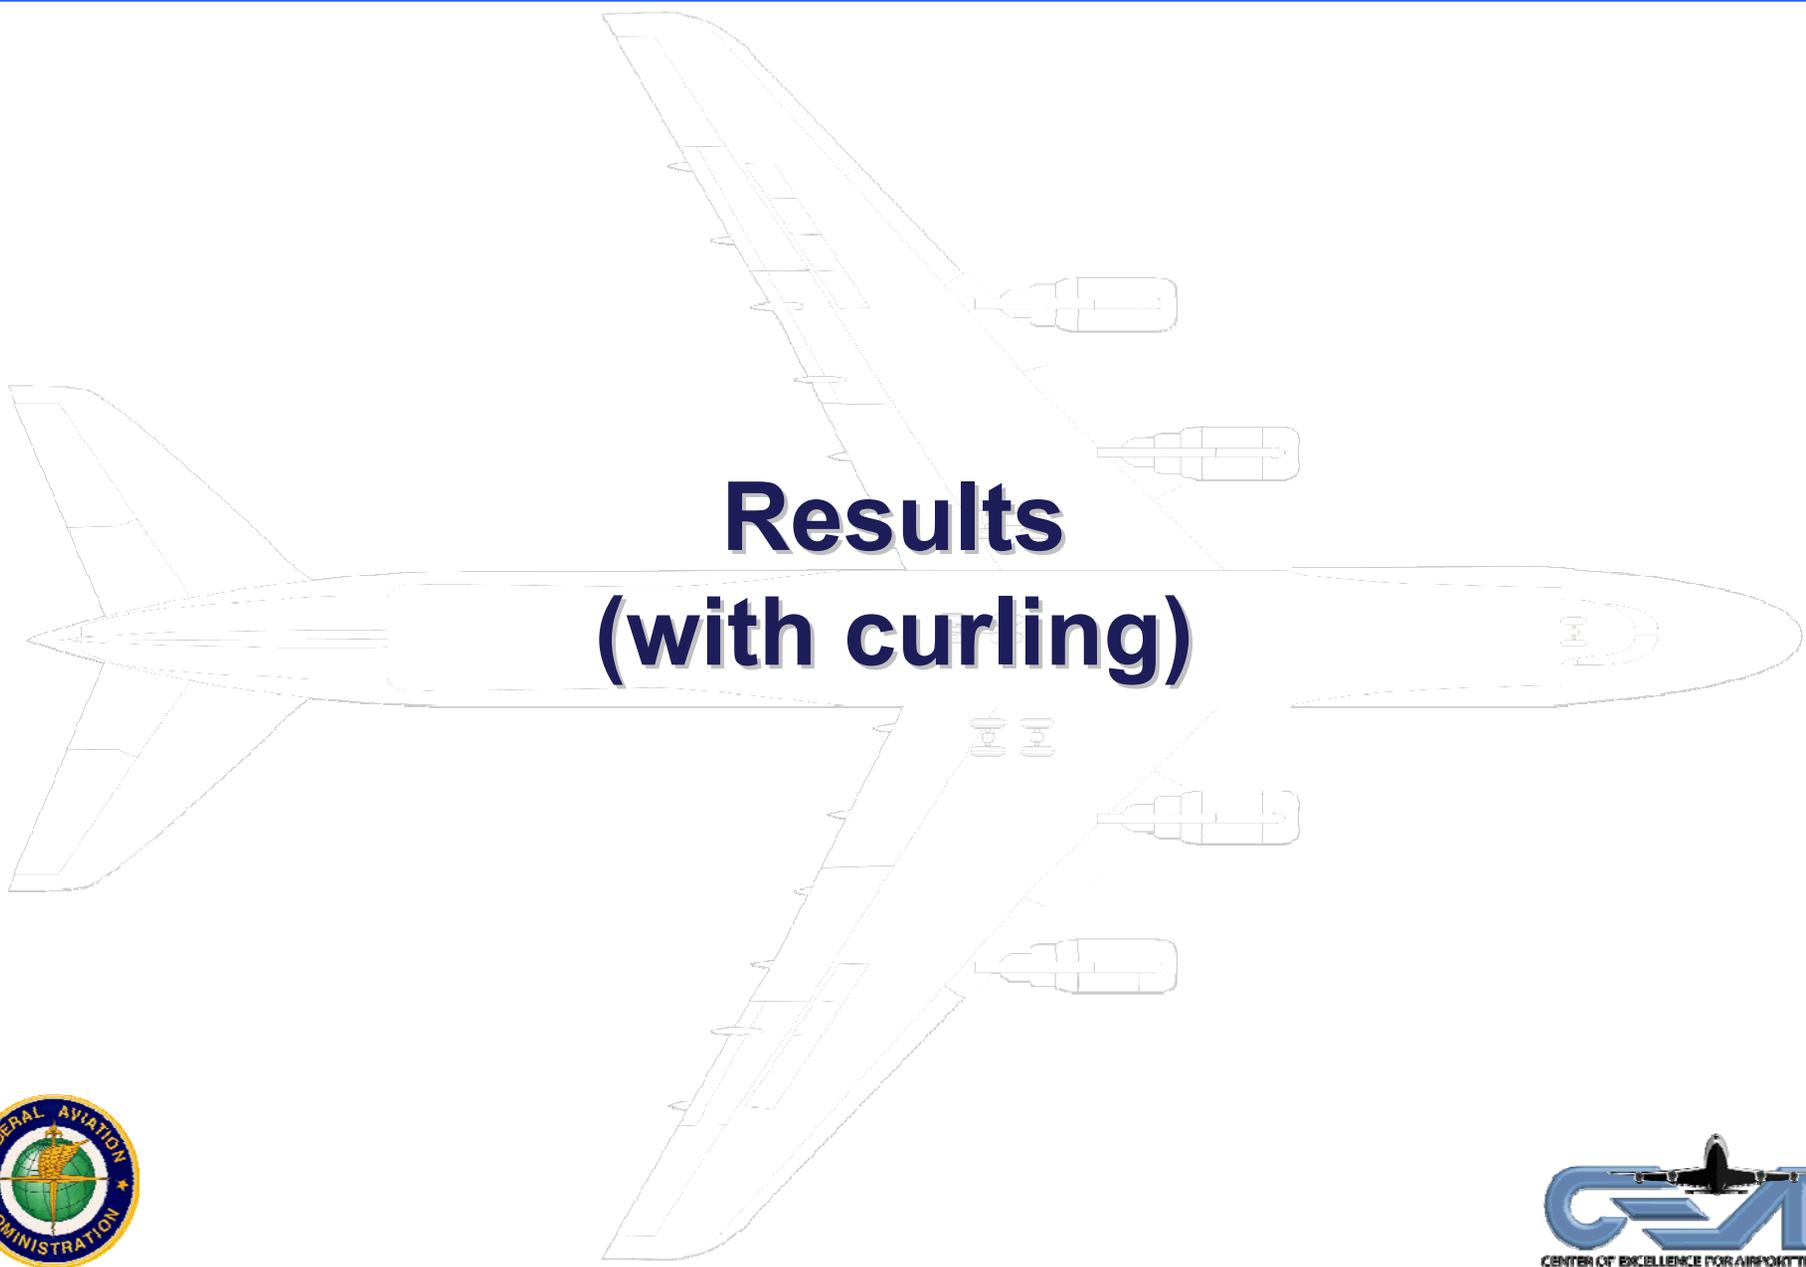

- L is not so important to top tensile stress

- LTE highly affects top tensile stress for all A/C
- Full gears affect A/C results, but B777

# Factorial results (t/b stress ratio)

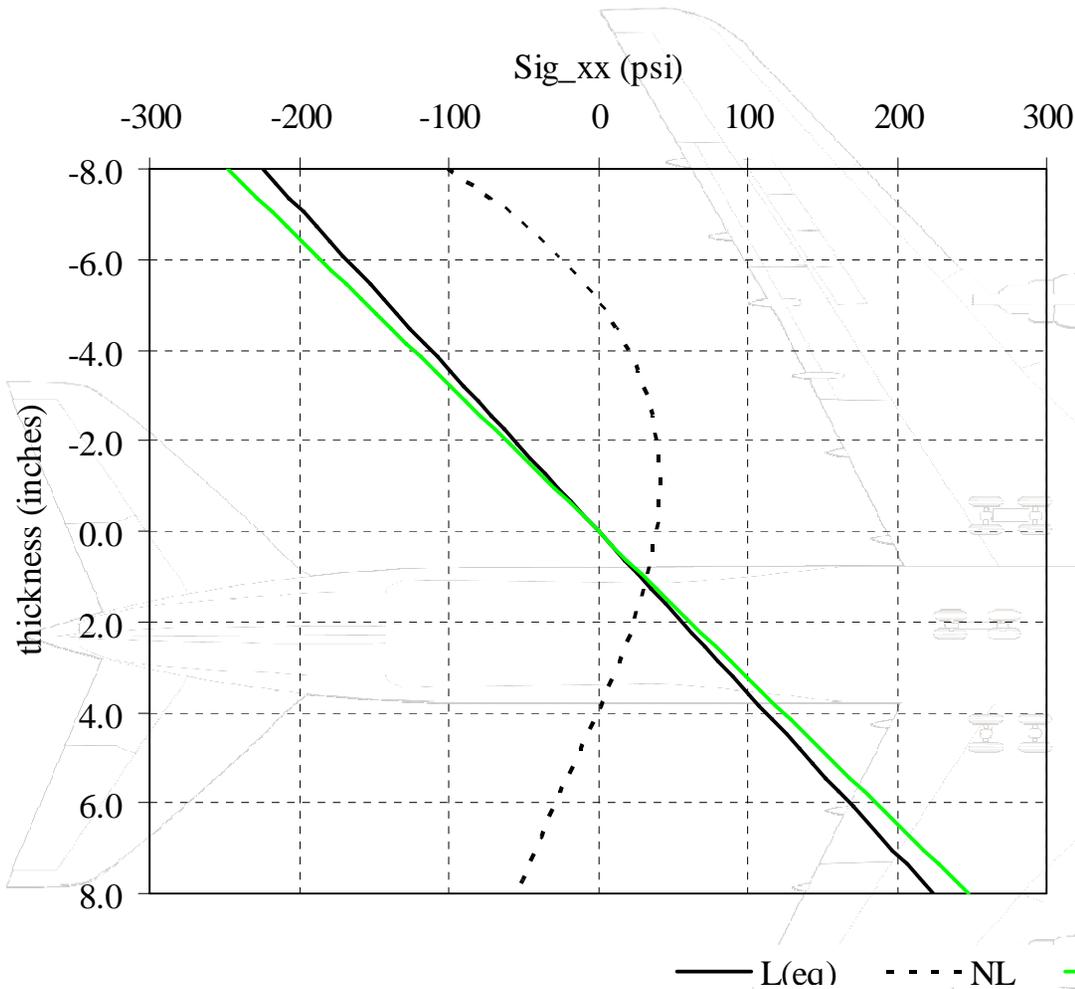

Same trend as in Top Stresses

# Results (with curling)

# Thermal Loads

| Nighttime profile | T (°F) |
|-------------------|--------|
| Top (Tt)          | 42     |
| Mid-top (Tmt)     | 50     |
| Mid-bottom (Tmb)  | 57     |
| Bottom (Tb)       | 59     |

$$\Delta T_{Lin} = -17.0^{\circ}\text{F}$$

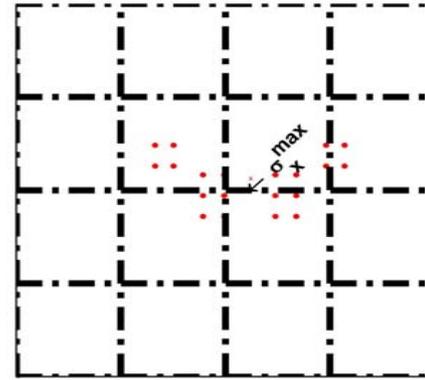

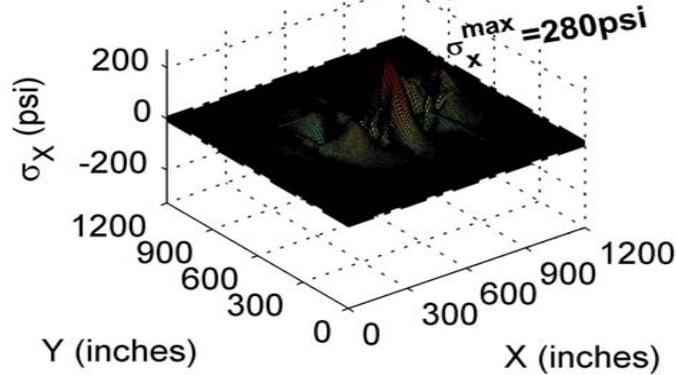

$$\Delta T_{eq} = -15.4^{\circ}\text{F}$$

And no thermal load applied:

$$\Delta T = 0.0^{\circ}\text{F}$$

# Conclusions

# Conclusions

- Finite element analysis shows consideration of full A/C gear IS NOT necessary for bottom tensile stresses prediction
  - Full A/C gear IS necessary for top tensile stress prediction
- Top to bottom tensile stress ratio higher for **full Aircraft analysis**
  - In most cases, critical top tensile stresses created when gears straddle multiple slabs
  - ↑ LTE then top to bottom tensile stress ratio decreases
  - The critical top tensile stress mostly occurred at transverse joint  
→ *longitudinal cracking* (e.g., NAPTF and Airbus tests)
  - *Slab size affect critical response position more than its magnitude for this analysis.*
- The analysis showed that the A-380 and the MD-11 induced higher top tensile stress values relative to B-777 and B-747; but B-747 and B-777 had much greater bottom tensile stresses.

# Conclusions

- *A-380 only a/c with t/b stress > 1.0 without curling but does not necessarily produce most critical stress of the 4 a/c analyzed!*
- Critical tensile stresses are can be greater at the top with curling.
- Full Aircraft and curling induce critical positions at the center of transverse joint (strong interaction with LTE).
- Almost all 3-D stress results were lower than 2-D ones:
  - especially lower LTE (crucial for top-down cracking);
  - Work still needed to validate top stresses in NIKE 3D
- **Top Tensile stresses are an interaction of the of slab configuration, moisture/temperature profile, full gear geometry and load levels.**

# THANK YOU
